1. Introduction

BlogMaster is a custom-built headless Content Management System (CMS) designed specifically for blog publishing. This platform empowers content creators with a robust backend to manage blog posts, drafts, and categories, coupled with a dynamic frontend for rendering content. By separating content management from content presentation, BlogMaster offers flexibility for future integrations and ensures a streamlined publishing workflow. It demonstrates a comprehensive understanding of API development, rich text editing, user authentication, and modern web architecture.

2. Key Features

- **Headless Architecture:** Provides a powerful API-driven backend for content management, allowing the frontend (or any other client) to consume content independently.
- **Rich Text Editor Integration:** Incorporates Quill.js to offer an intuitive and feature-rich editor for creating and formatting blog posts, supporting various text styles, images, and embeds.
- **Comprehensive Content Management:**
 - **Post Management:** Create, read, update, and delete blog posts.
 - **Drafts:** Save work in progress without publishing, allowing for review and refinement.
 - **Categories & Tags:** Organize content effectively for better navigation and searchability.
 - **Admin Panel:** A dedicated interface for authorized users to manage all aspects of the blog content.
- **Secure Authentication:** Utilizes JSON Web Tokens (JWT) for secure user authentication and authorization, protecting the CMS administration routes.
- **Dynamic Blog Frontend:** A React-based public-facing blog that dynamically fetches and renders published content from the CMS backend, ensuring a responsive and engaging reading experience.
- **Scalable & Flexible:** Built with modularity in mind, making it adaptable for future enhancements and integrations.
- **Optional: Static Export Feature:** Ability to generate static HTML files from published blog posts, offering performance benefits and simplified deployment for the public blog.

3. Technology Stack

BlogMaster is a full-stack application leveraging a powerful array of modern web technologies:

- **Backend (CMS API):**
 - **Runtime:** Node.js
 - **Web Framework:** Express.js (for building RESTful APIs for content management and serving the admin panel)
 - **Database:** MongoDB (NoSQL database for storing blog posts, user data, categories, and other content metadata)
 - **Authentication:** JWT (JSON Web Tokens) for secure, stateless user authentication.
- **Frontend (Admin Panel & Public Blog):**
 - **Framework:** React (for building interactive user interfaces for both the CMS admin panel and the public blog)
 - **Rich Text Editor:** Quill.js (integrated into the React admin panel for content creation)
 - **Styling:** Modern CSS practices or frameworks (e.g., Tailwind CSS, styled-components) for a clean and responsive design.
- **Architecture Overview: Headless CMS Data Flow**
- This diagram illustrates how content is managed in the CMS backend and delivered to the frontend application.
